

1 **ABSTRACT**

2 The present invention relates to a remote computer or
3 server management system for coupling a series of remote
4 computers to one or more user workstations allowing for
5 efficient location, error detection and/or general status
6 indication of the remote computers or servers. In
7 particular, computer interface modules connected to the
8 remote computers or servers include a signaling circuit to
9 emit an audible or visual signal upon detection of a
10 problem or upon receipt of a signal command from a user
11 trying to locate a particular remote computer.
12 Alternatively, the signaling circuit may transmit a message
13 to the user workstation to inform the user of a problem,
14 general status (e.g., of firmware upgrade), etc., which may
15 be displayed on the user's video monitor.
